

## BUS-BASED APPLIANCE REMOTE CONTROL

### BACKGROUND OF THE INVENTION

#### 1. Field of the Invention

5 The present invention relates to wireless remote control of appliances such as, for example, garage door openers.

#### 2. Background Art

10 Home appliances, such as garage door openers, security gates, home alarms, lighting, and the like, may conveniently be operated from a remote control. Typically, the remote control is purchased together with the appliance. The remote control transmits a radio frequency activation signal which is recognized by a receiver associated with the appliance. Aftermarket remote controls are gaining in popularity as such devices can offer functionality different from the original equipment's remote control. Such functionality includes decreased size, multiple appliance interoperability, increased performance, and the like. Aftermarket  
15 controllers are also purchased to replace lost or damaged controllers or to simply provide another remote control for accessing the appliance.

20 An example application for aftermarket remote controls are remote garage door openers integrated into an automotive vehicle. These integrated remote controls provide customer convenience, appliance interoperability, increased safety, and enhanced vehicle value. Present in-vehicle integrated remote controls provide a "universal" or programmable garage door opener which learns characteristics of an activation signal received from an existing transmitter then, when prompted by a user, generates a single activation signal having the same characteristics. One problem with such devices is the difficulty experienced by users in programming  
25 these devices. Another problem is that current designs are packaged as a single unit including control logic, user controls and radio frequency circuitry. This packaging

results in sub-optimal placement of certain components since they must be located together.

What is needed is a universal remote control that is easier to program. This remote control should be integrateable into an automotive vehicle using simple electronic circuits. The remote control should support placement of components at different locations within the vehicle.

### SUMMARY OF THE INVENTION

The present invention provides a universal remote control with components interconnected by a bus, permitting separate location.

A vehicle-based programmable appliance control system is provided. The system includes a vehicle-based data communication bus. A bus interface transmits an activation input signal over the data communication bus based on assertion of a user activation input. A radio frequency transmitter is remotely located from user activation inputs. Control logic generates control signals for transmitting an appliance activation signal based on receiving transmission of the activation input signal.

In an embodiment of the present invention, the system includes at least one user indicator remotely located from the transmitter. The control logic activates the user indicator over the data communication bus. Possible indicators include at least one indicator lamp, a graphical display, an audible sound generator, and the like.

In other embodiments of the present invention, activation inputs can include switches, a voice recognizer, a display control, and the like.

In still another embodiment of the present invention, the system includes a memory holding a plurality of activation schemes, each activation scheme providing characteristics for generating at least one appliance activation signal. A

data port communicates with the control logic over the data communication bus. The control logic receives data from the data port modifying the plurality of activation schemes.

A method of activating a remotely controlled appliance is provided.

- 5 An activation input is received from a user. An input signal representing the activation input is transmitted through a vehicle-based communication bus. The input signal is received from the vehicle-based bus at a location remote from where the activation input was received. A radio frequency activation signal based on the received input signal is transmitted.

- 10 A method of programming a vehicle-based remote control is provided. When programmed, the remote control transmits at least one activation signal for activating a remotely controlled appliance. At least one programming input is received from a user. The programming input specifies at least one of a plurality of activation signal characteristics. At least one programming signal representing the
- 15 programming input is transmitted through a vehicle-based communication bus. The programming signal is received from the vehicle-based bus at a location remote from where the programming input was received.

- In an embodiment of the present invention, the programming input includes at least one of a fixed code value, a selection of one of a plurality of
- 20 activation transmission schemes and an indication of whether the remotely controlled appliance is responsive to a fixed code activation signal or to a rolling code activation signal.

- A vehicle-based remote garage door opener is provided. The garage door opener includes a vehicle-based bus running throughout at least a portion of an
- 25 automotive vehicle. At least one user input device is in communication with the vehicle-based bus. A radio frequency transmitter transmits at least one of a plurality of different activation signals. Control logic, in communication with the vehicle-based bus and the transmitter, is remotely located from at least one user input device.

The control logic commands the transmitter to transmit at least one activation signal based on input received over the vehicle-based bus from the user input device.

5 A programmable control for an appliance is provided. The programmable control includes a serial data communication bus, a transmitter, a user programming input and control logic. The control logic implements a rolling code programming mode, a fixed code programming mode and an operating mode. In rolling code programming mode, the control logic generates and transmits a sequence of rolling code activation signals until user input indicates a successful rolling code transmission scheme. In fixed code programming mode, the control logic receives  
10 a fixed code from the user programming input then generates and transmits a sequence of fixed code activation signals until user input indicates a successful fixed code transmission scheme.

In a variation of the present invention, another programable control for an appliance is provided. The programmable control includes a serial data  
15 communication bus, a transmitter, a programming input, memory and control logic. For each of at least one channel, the control logic maintains a channel mode set initially to rolling code mode. The channel mode changes to a fixed code mode if the channel is trained to a fixed code received by the control logic from the programming input over the serial data communication bus.

20 In another variation of the present invention, yet another programmable control for an appliance is provided. The programmable control includes a serial data communication bus, a transmitter, a plurality of activation inputs, and control logic. The control logic is programmed to associate each of the activation inputs with at least one transmissions scheme. The control logic generates  
25 and transmits an activation signal based on each associated transmission scheme in response to receiving an activation signal from an asserted activation input over the serial data communication bus.

The above features, and other features and advantages of the present invention are readily apparent from the following detailed descriptions thereof when taken in connection with the accompanying drawings.

### BRIEF DESCRIPTION OF THE DRAWINGS

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT(S)

Referring to Figure 1, a block diagram illustrating an appliance control system according to an embodiment of the present invention is shown. An appliance control system, shown generally by 20, allows one or more appliances to be remotely controlled using radio transmitters. In the example shown, radio frequency remote controls are used to operate a garage door opener. However, the present invention may be applied to controlling a wide variety of appliances such as other mechanical barriers, lighting, alarm systems, temperature control systems, and the like.

Appliance control system 20 includes garage 22 having a garage door, not shown. Garage door opener (GDO) receiver 24 receives radio frequency control signals 26 for controlling a garage door opener. Activation signals have a transmission scheme which may be represented as a set of receiver characteristics. One or more existing transmitters (ET) 28 generate radio frequency activation signals 26 exhibiting the receiver characteristics in response to a user depressing an activation button.

A user of appliance control system 20 may wish to add a new transmitter to system 20. For example, a vehicle-based transmitter (VBT) including programable control 30 may be installed in vehicle 32, which may be parked in garage 22. Vehicle-based transmitter 30 generates a sequence of activation signals

34 which includes an activation signal having characteristics appropriate to activate activating garage door opener receiver 24. In the embodiment shown, programmable control 30 is mounted in vehicle 32. However, as will be recognized by one of ordinary skill in the art, the present invention applies to universal remote controls that may be mounted anywhere.

Referring now to Figure 2, a schematic diagram illustrating activation signal characteristics according to an embodiment of the present invention is shown. Information transmitted in an activation signal is typically represented as a binary data word, shown generally by 60. Data word 60 may include one or more fields, such as transmitter identifier 62, function indicator 64, code word 66, and the like. Transmitter identifier (TRANS ID) 62 uniquely identifies a remote control transmitter. Function indicator 64 indicates which of a plurality of functional buttons on the remote control transmitter were activated. Code word 66 helps to prevent misactivation and unauthorized access.

Several types of codes 66 are possible. One type of code is a fixed code, wherein each transmission from a given remote control transmitter contains the same code 66. In contrast, variable code schemes change the bit pattern of code 66 with each activation. The most common variable code scheme, known as rolling code, generates code 66 by encrypting a synchronization (sync) counter value. After each activation, the counter is incremented. The encryption technique is such that a sequence of encrypted counter values appears to be random numbers.

Data word 60 is converted to a baseband stream, shown generally by 70, which is an analog signal typically transitioning between a high voltage level and a low voltage level. Multilevel transmissions are also possible. Various baseband encoding or modulation schemes are known, including polar signaling, on-off signaling, bipolar signaling, duobinary signaling, Manchester signaling, and the like. Baseband stream 70 has a baseband power spectral density, shown generally by 72, centered around a frequency of zero.

Baseband stream 70 is converted to a radio frequency signal through a modulation process shown generally by 80. Baseband stream 70 is used to modulate one or more characteristics of carrier 82 to produce a broadband signal, shown generally by 84. Modulation process 80, mathematically illustrated by multiplication in Figure 2, implements a form of amplitude modulation commonly referred to as on-off keying. As will be recognized by one of ordinary skill in the art, many other modulation forms are possible, including frequency modulation, phase modulation, and the like. In the example shown, baseband stream 70 forms envelope 86 modulating carrier 82. As illustrated in broadband power spectral density 88, the effect in the frequency domain is to shift baseband power spectral density 72 up in frequency so as to be centered around the carrier frequency,  $f$ , of carrier 82.

Referring now to Figure 3, a block diagram illustrating rolling code operation that may be used with the present invention is shown. Remotely controlled systems using rolling code require crypt key 100 in both the transmitter and the receiver for normal operation. In a well-designed rolling code scheme, crypt key 100 is not transmitted from the transmitter to the receiver. Typically, crypt key 100 is generated using key generation algorithm 102 based on transmitter identifier 62 and a manufacturing (MFG) key 104. Crypt key 100 and transmitter identifier 62 are then stored in a particular transmitter. Counter 106 is also initialized in the transmitter. Each time an activation signal is sent, the transmitter uses encrypt algorithm 108 to generate rolling code value 110 from counter 106 using crypt key 100. The transmitted activation signal includes rolling code 110 and transmitter identifier 62.

A rolling code receiver is trained to a compatible transmitter prior to normal operation. The receiver is placed into a learn mode. Upon reception of an activation signal, the receiver extracts transmitter identifier 62. The receiver then uses key generation algorithm 102 with manufacturing key 104 and received transmitter identifier 62 to generate crypt key 100 identical to the crypt key used by the transmitter. Newly generated crypt key 100 is used by decrypt algorithm 112 to decrypt rolling code 110, producing counter 114 equal to counter 106. The

receiver then saves counter 114 and crypt key 100 associated with transmitter identifier 62. As is known in the encryption art, encrypt algorithm 108 and decrypt algorithm 112 may be the same algorithm.

5 In normal operation, when the receiver receives an activation signal, the receiver first extracts transmitter identifier 62 and compares transmitter identifier 62 with all learned transmitter identifiers. If no match is found, the receiver rejects the activation signal. If a match is found, the receiver retrieves crypt key 100 associated with received transmitter identifier 62 and decrypts rolling code 110 from the received activation signal to produce counter 114. If received counter 106  
10 matches counter 114 associated with transmitter identifier 62, activation proceeds. Received counter 106 may also exceed stored counter 114 by a preset amount for successful activation.

Another rolling code scheme generates crypt key 100 based on manufacturing key 104 and a “seed” or random number. An existing transmitter  
15 sends this seed to an appliance receiver when the receiver is placed in learn mode. The transmitter typically has a special mode for transmitting the seed that is entered, for example, by pushing a particular combination of buttons. The receiver uses the seed to generate crypt key 100. As will be recognized by one of ordinary skill in the art, the present invention applies to the use of a seed for generating a crypt key  
20 as well as to any other variable code scheme.

Referring now to Figure 4, a schematic diagram illustrating a fixed code setting which may be used according to an embodiment of the present invention is shown. Fixed code systems typically permit a user to set the fixed code value through a set of DIP switches or jumpers. For example, fixed code receiver 24 and  
25 transmitter 28 may each include printed circuit board 120 having a plurality of pins, one of which is indicated by 122, together with support electronics, not shown. Pins 122 are arranged in a grid having three rows and a number of columns equal to the number of bits in the fixed code value. A jumper, one of which is indicated by 124, is placed in each column straddling either the first and second pins or the second and  
30 third pins. One position represents a logical “1” and the other position represents

a logical "0." Various alternative schemes are also possible. For example, two rows may be used, with the presence or absence of jumper 124 indicating one of the logical binary values. As another alternative, a set of DIP switches may be used with "up" representing one binary value and "down" representing the other.

5                   In various embodiments of the present invention, a user is asked to read the fixed code value from existing transmitter 28 or appliance receiver 24 and enter this fixed code value into programmable control 30. A difficulty experienced by users asked to read such values is in determining from which end to start. Another difficulty is in determining which setting represents a binary "1" and which  
10                   setting represents a binary "0." For example, the pattern represented in Figure 4 may be interpreted as "00011010," "11100101," "01011000" or "10100111." Entering an incorrect value can frustrate a user who is not sure why he cannot program his fixed code transmitter. To rectify this situation, embodiments of the present invention transmits fixed code activation signals based on the fixed code  
15                   value as entered by the user and at least one of a bitwise reversal of the fixed code, a bitwise inversion of the fixed code, and both a bitwise reversal and inversion.

Referring now to Figure 5, a block diagram illustrating a programmable remote control according to an embodiment of the present invention is shown. Programmable control 30 includes control logic 130 and a transmitter  
20                   section, shown generally by 132. Transmitter section 132 includes variable frequency oscillator 134, modulator 136, variable gain amplifier 138 and antenna 140. For each activation signal in sequence of activation signals 34, control logic 130 sets the carrier frequency of the activation signal generated by variable frequency oscillator 134 using frequency control signal 142. Control logic 132  
25                   modulates the carrier frequency with modulator 136, modeled here as a switch, to produce an activation signal which is amplified by variable gain amplifier 138. Modulator 136 may be controlled by shifting a data word serially onto modulation control signal 144. Other forms of modulation are possible, such as frequency modulation, phase modulation, and the like. Variable gain amplifier 138 is set to  
30                   provide the maximum allowable output power to antenna 140 using gain control signal 146.

Control logic 130 receives user input 148 providing fixed code programming information and activation inputs. User input 148 may be implemented with one or more switches directly connected to control logic 130. Alternatively, user input 148 may be provided through remote input devices connected to control logic 130 via a serial bus. Control logic 130 generates one or more user outputs 150. User outputs 150 may include indicator lamps directly connected to control logic 130 and/or remote display devices connected to control logic 130 through a serial bus.

Referring now to Figure 6, a schematic diagram illustrating control logic and a user interface according to an embodiment of the present invention is shown. Control logic 130 and electronics for a user interface, shown generally by 160, can be implemented with microcontroller 162. User interface 160 includes at least one activation input, shown generally by 164. Three activation inputs 164 are shown, labeled "A," "B" and "C." Each activation input 164 is implemented with one pushbutton switch 166. Each pushbutton switch 166 provides a voltage signal to a digital input (DI) for microcontroller 162. User interface 160 also includes one indicator lamp 168 associated with each activation input 164. Each indicator lamp 168 may be implemented using one or more light emitting diodes supplied by a digital output (DO) from microcontroller 162.

User interface 160 can include a plurality of DIP switches, one of which is indicated by 170, for implementing programming input 172. DIP switches 170 are set to match the fixed code value from fixed code appliance receiver 24 or associated existing transmitter 28. Microcontroller 162 reads DIP switches 170 using parallel bus 174. Alternatively, programming input 172 may be implemented using pushbutton switches 166 as will be described in greater detail below.

Microcontroller 162 generates control signals determining characteristics of transmitted activation signals. Frequency control signal 142 is delivered from an analog output (AO) on microcontroller 162. For example, if variable frequency oscillator 134 is implemented using a voltage controlled oscillator, varying the voltage on frequency control signal 142 will control the carrier

frequency of the activation signal. Frequency control signal 142 may also be one or more digital outputs used to select between fixed frequency sources. Modulation control signal 144 is provided by a digital output on microcontroller 162. The fixed or rolling code data word is put out on modulation control 144 in conformance with the baseband modulation and bit rate characteristics of the activation scheme being implemented. Microcontroller 162 generates gain control signal 146 as an analog output for controlling the amplitude of the activation signal generated. As will be recognized by one of ordinary skill in the art, analog output signals may be replaced by digital output signals feeding an external digital-to-analog converter.

Referring now to Figure 6, a memory map for implementing operating modes according to an embodiment of the present invention is shown. A memory map, shown generally by 190, represents the allocation of memory for data tables used by programmable control 30. Preferably, this data is held in non-volatile memory such as flash memory. Memory map 190 includes channel table 192, mode table 194 and scheme table 196.

Channel table 192 includes a channel entry, one of which is indicated by 198, for each channel supported by programmable control 30. Typically, each channel corresponds to a user activation input. In the example illustrated in Figure 6, three channels are supported. Each channel entry 198 has two fields, mode indicator 200 and fixed code 202. Mode indicator 200 indicates the mode programmed for that channel. In the embodiment shown, a zero in mode indicator 200 indicates rolling code mode. A non-zero integer in mode indicator 200 indicates a fixed code mode with a code size equal to the integer value. For example, the first channel (CHAN1) has been programmed for eight-bit fixed code operation, the second channel (CHAN2) has been programmed for rolling code operation and the third channel (CHAN3) has been programmed for ten-bit fixed code operation. Fixed code value 202 holds the programmed fixed code for a fixed code mode. Fixed code value 202 may also hold function code 64 in fixed code modes. Fixed code value 202 may hold function code 64 or may not be used at all in a channel programmed for a rolling code mode.

Mode table 194 contains an entry for each mode supported. The four entries illustrated are rolling code entry 204, eight-bit fixed code entry 206, nine-bit fixed code entry 208 and ten-bit fixed code entry 210. Each entry begins with mode indicator 200 for the mode represented, the next value is scheme count 212 indicating the number of schemes to be sequentially transmitted in that mode. Following scheme count 212 is a scheme address 214 for each scheme. The address of the first entry of mode table 194 is held in table start pointer 216 known by control logic 130. When accessing data for a particular mode, control logic 130 searches through mode table 194 for mode indicator 200 matching the desired mode. The use of mode indicators 200 and scheme counts 212 provides a flexible representation for adding new schemes to each mode and adding new modes to mode table 194.

Scheme table 196 holds characteristics and other information necessary for generating each activation signal in sequence of activation signals 34. Scheme table 196 includes a plurality of rolling code entries, one of which is indicated by 220, and a plurality of fixed code entries, one of which is indicated by 222. Each rolling code entry 220 includes transmitter identifier 62, counter 106, crypt key 100, carrier frequency 224, and subroutine address 226. Subroutine address 226 points to code executable by control logic 130 for generating an activation signal. Additional characteristics may be embedded within this code. Each fixed code entry 222 includes carrier frequency 224 and subroutine address 226. Next pointer 228 points to the next open location after scheme table 196. Any new schemes received by control logic 130 may be appended to scheme table 196 using next pointer 228.

Memory map 190 illustrated in Figure 6 implements a single rolling code mode and three fixed code modes based on the fixed code size. Other arrangement of modes are possible. For example, more than one rolling code modes may be used. Only one fixed code mode may be used. If more than one fixed code mode is used, characteristics other than fixed code size may be used to distinguish between fixed code modes. For example, fixed code schemes may be grouped by carrier frequency, modulation technique, baseband modulation, and the like.

In other alternative embodiments, channel table 192 can hold different values for channel entries 198. For example, each channel entry 198 could include scheme address 214 of a successfully trained scheme as well as fixed code value 202.

5                   Referring now to Figures 8-16, flow charts illustrating programmable control operation according to embodiments of the present invention are shown. As will be appreciated by one of ordinary skill in the art, the operations illustrated are not necessarily sequential operations. Similarly, operations may be performed by software, hardware, or a combination of both. The present invention transcends any  
10 particular implementation and the aspects are shown in sequential flowchart form for ease of illustration.

                  Referring to Figure 8, a top level flowchart is shown. System initialization occurs, as in block 240. Control logic 130 is preferably implemented with a microcontroller. Various ports and registers are typically initialized on power  
15 up. A check is made to determine if this is a first power up occurrence, as in block 242. If so, the mode for each channel is set to rolling code, as in block 244. The system then waits for user input, as in block 246. This waiting may be done either with power applied or removed.

                  Referring now to Figure 9, a flowchart illustrating response to user  
20 input is shown. The user input is examined, as in block 250. A check is made for reset input, as in block 252. If so, a reset routine is called, as in block 254. If not, a check is made for activation input, as in block 256. If so, an activation routine is called, as in block 258. If not, a check is made to determine if fixed code training input has been received, as in block 260. If so, a fixed code training routine is  
25 called, as in block 262. Other input options are possible, such as placing programmable control 30 into a download mode for receiving data related to adding or changing activation schemes.

                  Interpreting user input depends upon the type of user input supported by programmable control 30. For a simple pushbutton system, a button depression

of short duration may be used to signify activation input for the channel assigned to the button. Holding the button for a moderate length of time may be used to signify fixed training input. Holding the button for an extended period of time may be used to indicate reset input. Alternatively, different combinations of buttons may be used to place programmable control 30 into various modes of operation.

Referring now to Figure 10, a flowchart illustrating an activation routine is shown. A determination is made as to which activation input was asserted, as in block 270. For the selected channel, a check is made to determine under which mode the activation input channel is operating, as in block 272. This determination can be accomplished by examining channel table 192 as described above. For a fixed code mode, the stored fixed code is retrieved, as in block 274. A loop is executed for each scheme associated with the fixed code mode. Characteristics for the next scheme are loaded, as in block 276. This may be accomplished, for example, by obtaining a pointer to an entry in scheme table 196. A data word is formed using the fixed code, as in block 278. The frequency is set, as in block 280. The data word is modulated and transmitted, as in block 282. A check is made to determine if any schemes remain, as in block 284. If so, blocks 276, 278, 280 and 282 are repeated. If not, the activation routine terminates.

Considering again block 272, if the channel mode corresponding to the asserted input is a rolling code mode, a rolling code activation signal loop is entered. Characteristics of the next rolling code scheme are loaded, as in block 286. The synchronization counter associated with the current scheme is incremented, as in block 288. The incremented counter value is also stored. The synchronization counter is encrypted using the crypt key to produce a rolling code value, as in block 290. A data word is formed using the rolling code value, as in block 292. The carrier frequency is set, as in block 294. The data word is modulated and transmitted, as in block 296. A check is made to determine if any schemes remain in the rolling code mode, as in block 298. If so, blocks 286, 288, 290, 292, 294 and 296 are repeated. If no schemes remain, the activation routine is terminated.

Referring now to Figure 11, a flow chart illustrating fixed code training is shown. The user is prompted for input, as in block 300. Prompting may be accomplished, for example, by flashing one or more of indicator lamps 168. Alternatively, other audio and/or visual prompts may be provided to the user as will be described in greater detail below. User input is received, as in block 302. The user enters a fixed code value. This value may be entered in parallel such as, for example, through the use of DIP switches 170. The user may also enter fixed code information through one or more remote user inputs as will be described in greater detail below. Activation inputs 164 provide another means for inputting a fixed code value. In a three button system, a first button can be used to input a binary "1," a second button can be used to input a binary "0" and a third button can be used to indicate completion.

Blocks 304 through 314 describe serially inputting a fixed code value using activation inputs 164. A check is made to determine if an end of data input was received, as in block 304. If not, a check is made to see if the input value was a binary "1," as in block 306. If so, a binary "1" is appended to the fixed code value, as in block 308, and an indication of binary "1" is displayed, as in block 310. This display may be, for example, illuminating indicator lamp 168 associated with activation input 164 used to input the binary "1." Returning to block 306, if a binary "1" was not input, a binary "0" is appended to the fixed code, as in block 312. A display indicating a binary "0" is provided, as in block 314.

Returning now to block 304, once the fixed code value has been received, a loop is entered to generate a sequence of at least one fixed code activation signal. The next fixed code scheme is loaded, as in block 316. Preferably, this scheme is based on the number of bits in the received fixed code. A data word is formed based on the loaded fixed scheme, as in block 318. This data word includes the received fixed code either as received or as a binary modification of the received fixed code. The carrier frequency is set based on the loaded scheme, as in block 320. The carrier is modulated and the resulting activation signal transmitted, as in block 322. A check is made to determine if any schemes remain, as in block 324. If so, the operations indicated in blocks 316, 318, 320 and 322 are

repeated. If not, the user is prompted for input and the input received, as in block 326. One possible indication from the user is a desire to reload the fixed code, as in block 328. If so, the operation returns to block 300. If not, a check is made to determine if user input indicates success, as in block 330. If so, the fixed code is stored associated with a specified activation input and the mode is changed to fixed,  
5 as in block 332.

Referring now to Figure 12, a reset routine is shown. Each activation input channel is set to rolling mode, as in block 340. The user is notified of successful reset, as in block 342. Once again, a pattern of flashing indicator lamps  
10 may be used for this indication. Alternatively, if a reset routine is entered by asserting a particular user input 164 such as, for example, by depressing pushbutton switch 166 for an extended period of time, then only the mode corresponding to that user input need be reset by the reset routine.

Referring now to Figures 13-16, flowcharts illustrating alternative programmable controller operation according to embodiments of the present invention are shown. In Figure 13, user input processing including rolling code training is provided. User input is examined, as in block 350. A determination is made as to whether or not the input indicates a reset, as in block 352. If so, a reset  
15 routine is called, as in block 354. A determination is made as to whether or not the input specified rolling code training, as in block 356. If so, a rolling code training routine is called, as in block 358. If not, a determination is made as to whether fixed code training input was received, as in block 360. If so, a fixed code training routine is called, as in block 362. If not, a determination is made as to whether or  
20 not one of at least one activation inputs was received, as in block 364. If so, an activation routine is called, as in block 366. Other inputs are possible such as, for example, input specifying a data download for adding or changing activation signal schemes or modes.  
25

Referring now to Figure 14, a rolling code training routine is provided. The routine includes a loop in which one or more rolling code activation  
30

signals are sent as a test. A user provides feedback regarding whether or not the target appliance was activated.

5           The next rolling code scheme in the sequence is loaded, as in block 370. The sync counter, upon which the rolling code is based, is initialized, as in block 372. The sync counter is encrypted according to the current scheme to generate a rolling code value, as in block 374. A data word is formed including the generated rolling code value, as in block 376. The carrier is set, as in block 378. The data word is used to modulate the carrier according to the current scheme, as in block 380. The resulting activation signal is then transmitted.

10           The guess-and-test approach requires interaction with the user. In one embodiment, the test pauses until either a positive input or a negative input is received from the user, as in block 382. In another embodiment, the test pauses for a preset amount of time. If no user input is received within this time, the system assumes the current test has failed. A check for success is made, as in block 384.  
15   If the user indicates activation, information indicating the one or more successful schemes is saved, as in block 386. This information may be associated with a particular user activation input. The user may assign a particular user activation input as part of block 382 or may be prompted to designate an activation input as part of block 386.

20           Returning to block 384, if the user did not indicate successful activation, a check is made to determine if any schemes remain, as in block 390. If not, a failure indication is provided to the user, as in block 392. This indication may consist of a pattern of flashing indicator lamps, an audio signal, a pattern on a video display, or the like. If any schemes remain, the test loop is repeated.

25           The training routine illustrated in Figure 14 indicates a single activation signal is generated for each test. However, multiple activation signals may be generated and sent with each test. In one embodiment, further tests are conducted to narrow down which scheme or schemes successfully activated the appliance. In another embodiment, the programmable control stores information indicating the

successful sequence so that the successful sequence is retransmitted each time the appropriate activation input is received.

Referring now to Figure 15, an alternative fixed code training routine is provided. The user is prompted to input a fixed code value, as in block 400.

5 User input is received, as in block 402. As previously discussed, the fixed code value may be input serially or parallelly through one or more of a variety of inputs including specially designated programming switches, activation inputs, remote input devices, and the like. If the fixed code value is serially entered by the user, a check is made to determine end of data, as in block 404. If input did not indicate end of

10 data, a check is made to determine if a binary "1" was input, as in block 406. If so, a binary "1" is appended to the fixed code, as in block 408, and a binary "1" is displayed to the user, as in block 410. If not, a binary "0" is appended to the fixed code, as in block 412, and a binary "0" is displayed to the user, as in block 414.

Returning to block 404, once the fixed code value is received a guess-

15 and-test loop is entered. A display may be provided to the user indicating that the test is in progress, as in block 416. Information describing the next fixed code scheme is loaded, as in block 418. A data word is formed containing the fixed code, as in block 420. The carrier frequency is set, as in block 422. The data word is used to modulate the carrier, producing an activation signal, which is then

20 transmitted, as in block 424. User input regarding the success of the test is received, as in block 426. Once again, the system may pause for a preset amount of time and, if no input is received, assume that the test was not successful. Alternatively, the system may wait for user input specifically indicating success or failure. A check is made to determine whether or not the test was successful, as in block 428. If so,

25 information specifying the one or more successful schemes and the fixed code value are saved. This information may be associated with a particular activation input specified by the user. In addition, the mode is changed to fixed mode for the selected activation input. If success was not indicated, a check is made to determine if any schemes remain, as in block 432. If not, failure is indicated to the user, as in

30 block 434. If any schemes remain, the test loop is repeated.

The guess-and-test scheme illustrated in Figure 15 generates and transmits a single activation signal with each pass through the loop. However, as with rolling code training, more than one fixed code activation signal may be sent within each test. Once success is indicated, the user may be prompted to further  
5 narrow the selection of successful activation signals. Alternatively, information describing the sequence can be stored and the entire sequence retransmitted upon receiving an activation signal to which the sequence is associated.

Referring now to Figure 16, a flow chart illustrating an activation routine according to an embodiment of the present invention is shown. Information  
10 associated with an asserted activation input is retrieved, as in block 440. A check is made to determine if the mode associated with the activation channel is rolling, as in block 442. If so, the sync counter is loaded and incremented, as in block 444. The sync counter is encrypted to produce a rolling code value, as in block 446. A data word is formed including the rolling code value, as in block 448. The carrier  
15 frequency is set, as in block 450. The data word is used to modulate the carrier frequency, producing an activation signal which is then transmitted, as in block 452. The sync counter is stored, as in block 454.

Returning to block 442, if the mode is not rolling, the stored fixed code value is retrieved, as in block 456. A data word is formed including the  
20 retrieved fixed code, as in block 458. The carrier frequency is set, as in block 460. The data word is used to modulate the carrier, producing an activation signal which is then transmitted, as in block 462.

Various embodiments for programming to fixed and rolling code appliances and for responding to activation input for fixed and rolling code  
25 appliances have been provided. As will be recognized by one of ordinary skill in the art, these methods may be combined in any manner. For example, programmable control 30 may implement a system which transmits every rolling code activation signal upon activation of a rolling code channel and uses guess-and-test training for programming a fixed code channel. As another example,  
30 programmable control 30 may be configured for guess-and-test training using every

possible rolling code scheme but, when training for fixed code, generates and transmits activation signals based on only those fixed code schemes known to be used with a fixed code value having a number of bits equal to the number of bits of the fixed code value entered by the user.

5                   Referring now to Figure 17, a drawing illustrating a vehicle interior that may be used to program a programmable controller according to an embodiment of the present invention is shown. A vehicle interior, shown generally by 470, includes console 472 having one or more of a variety of user interface components. Graphical display 474 and associated display controls 476 provide an interactive  
10                   device for HVAC control, radio control, lighting control, vehicle status and information display, map and positioning display, routing and path planning information, and the like. Display 204 can provide instructions for programming and using programmable control 30. Display 474 can also provide status and control  
15                   feedback to the user in training and operating modes. Display controls 476 including, if available, touch-screen input provided by display 474 can be used to provide programming input. In addition, display 474 and controls 476 may be used as activation inputs for programmable control 30.

                  Console 472 includes numeric keypad 478 associated with an in-vehicle telephone. For fixed code training, numeric keypad 478 can be used to enter  
20                   the fixed code value. Programmable control 30 may also recognize one or a sequence of key depressions on keypad 478 as an activation input.

                  Console 472 may include speaker 480 and microphone 482 associated with an in-vehicle telephone, voice activated control system, entertainment system, audible warning system, and the like. Microphone 482 may be used to provide  
25                   activation and/or programming inputs. Speaker 480 can provide audio feedback during programming and/or activation modes. In addition, microphone 482 and speaker 480 may be used to provide programming instructions, interactive help, and the like.

Referring now to Figure 18, a block diagram illustrating a bus-based automotive vehicle electronic system according to an embodiment of the present invention is shown. An electronic system, shown generally by 490, includes interconnecting bus 492. Automotive communication buses may be used to interconnect a wide variety of components within the vehicle, some of which may function as interface devices for programming or activating appliance controls. Many standards exist for specifying bus operations such as, for example, SAE J-1850, Controller Area Network (CAN), and the like. Various manufacturers provide bus interfaces 224 that handle low level signaling, handshaking, protocol implementation and other bus communication operations.

Electronics system 490 includes programmable control 30. Programmable control 30 includes at least control logic 130 and transmitter (TRANS) 132. Control logic 130 accesses memory 496, which holds a plurality of activation schemes. Each scheme describes activation control signals used by control logic 130 to transmit activation signals by transmitter 132. User interface 160 interfaces control logic 130 with user activation inputs and outputs, not shown. User interface 160 may be directly connected to control logic 130 or may be connected through bus 492. This latter option allows control logic 130 and transmitter 132 to be located anywhere within vehicle 32.

Electronics system 490 may include wireless telephone 498 interfaced to bus 492. Telephone 498 can receive input from keypad 478 and from microphone 482 through microphone input 500. Telephone 498 provides audio output to speaker 480 through speaker driver 502. Telephone 498 may be used to contact a human or automated help system and may also be used as a data port to download scheme and software updates into memory 496. Keypad 478 may be directly interfaced to bus 492 allowing keypad 478 to provide user input to control logic 130. Microphone 482 provides voice input through microphone input 500 to speech recognizer 504. Speech recognizer 504 is interfaced to bus 492 allowing microphone 482 to provide input for control logic 130. Sound generator 506 supplies signals for audible reproduction to speaker 480 through speaker driver 502. Sound generator 506 may be capable of supplying tone-based signals and/or artificial

speech signals. Sound generator 506 is interfaced to bus 492 allowing control logic 130 to send audible signals to a user.

Display controller 508 generates signals controlling display 474 and accepts display control input 476. Display controller 508 is interfaced to bus 492  
5 allowing control logic 130 to initiate graphical output on display 474 and receive user input from controls 476.

Radio 510 is interfaced to bus 492 allowing control logic 130 to initiate display through radio 510 and receive input from controls on radio 510. For example, volume and tuning controls on radio 510 may be used to enter a fixed code value. Rotating the volume knob may sequentially cycle through the most significant  
10 bits of the code and rotating the tuning knob may sequentially cycle through the least significant bits of the code. Pushing a radio control can then send the fixed code to control logic 130.

Wireless transceiver 512 is interfaced to bus 492 through bus interface  
15 494. Wireless transceiver 512 communicates with wireless communication devices, represented by 514 and 516, such as portable telephones, personal digital assistants, laptop computers, and the like, through infrared or short range radio frequency signals. Various standards exist for such communications including IEEE 802.11, Bluetooth, IrDA, and the like. Transceiver 512 is interfaced to bus 492, permitting  
20 wireless devices 514, 516 to provide input to and receive output from control logic 130. Wireless devices 514, 516 may also be used as a data port to upload code and scheme data into memory 496 and/or to exchange data with programmable control 30 for assisting in programming control 30.

Data port 518 implements a data connection interfaced to bus 492  
25 through bus interface 494. Data port 518 provides a plug or other interface for exchanging digital information. One or more standards may be supported, such as IEEE 1394, RS-232, SCSI, USB, PCMCIA, and the like. Proprietary information exchange or vehicle diagnostic ports may also be supported. Data port 518 may be

used to upload code and scheme data into memory 496 and/or exchange data with programmable control 30 for assisting in programming control 30.

Referring now to Figure 19, a block diagram illustrating distributed control elements interconnected by a vehicle bus according to an embodiment of the present invention is shown. Bus 492 is a CAN bus. Bus interface 494 may be implemented with CAN transceiver 530 and CAN controller 532. CAN transceiver 530 may be a PCA82C250 transceiver from Philips Semiconductors. CAN controller 232 may be a SJA 1000 controller from Philips Semiconductors. CAN controller 232 is designed to connect directly with data, address and control pins of certain microcontrollers such as, for example, an 80C51 family microcontroller from Intel Corporation.

In the example shown, control logic 130 and transmitter 132 are supported by a first bus interface 494. Activation inputs 164 provide inputs to, and indicators 168 are driven by, microcontroller 534 which is supported by a second bus interface 494. Programming input switches 172 are connected in parallel to microcontroller 536 which is supported by a third bus interface 494. Serial bus 492 and separate interfaces 494 permit various components of programmable control 30 to be placed in different locations within vehicle 32. One advantage of separate location is that transmitter 132 need not be placed near user controls 164, 168, 172. Instead, transmitter 132 may be placed at a location optimizing radio frequency transmission from vehicle 32. Another advantage of separately locating components of programmable control 30 is to facilitate the design of vehicle interior 470. For example, activation inputs 164 and indicator lamps 168 may be located for easy user access such as in an overhead console, a visor, a headliner, and the like. Programming input controls 172, which would be infrequently used, may be placed in a more hidden location such as inside of a glove box, trunk, storage compartment, and the like. Yet another advantage of a bus-based programmable control 30 is the ability to interface control logic 130 with a wide variety of vehicle controls and displays.

While embodiments of the invention have been illustrated and described, it is not intended that these embodiments illustrate and describe all possible forms of the invention. Rather, the words used in the specification are words of description rather than limitation, and it is understood that various changes may be  
5 made without departing from the spirit and scope of the invention.
